

# Protein Misfolding: Therapeutic Implications

---

Opportunities for Therapeutic and Diagnostic  
Development for Degenerative Diseases

**Charles Glabe, Ph.D.**

# Overview

- Conformation-dependent antibodies specifically recognize toxic soluble amyloid oligomers and distinguish them from natively folded protein, denatured monomer and amyloid fibrils.
- This provides a means of specifically targeting soluble amyloid oligomers through immunization.
- Immunization may be an effective treatment for AD and other degenerative diseases.

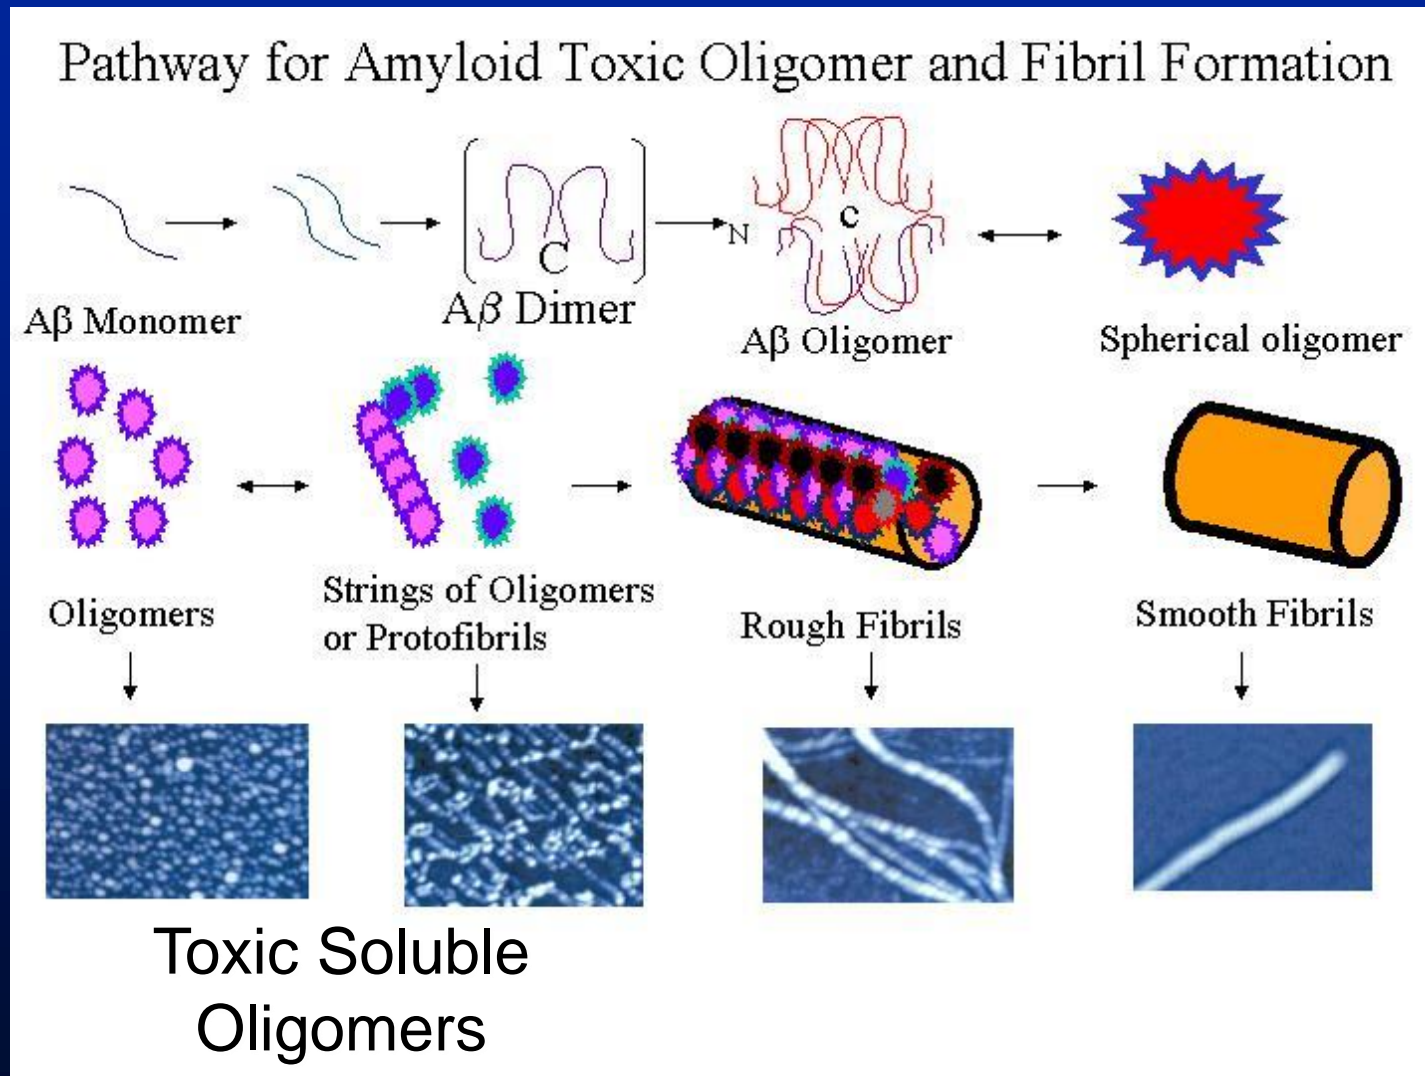

Soluble amyloid oligomers are suspected to be a causative agent in a broad range of degenerative diseases.

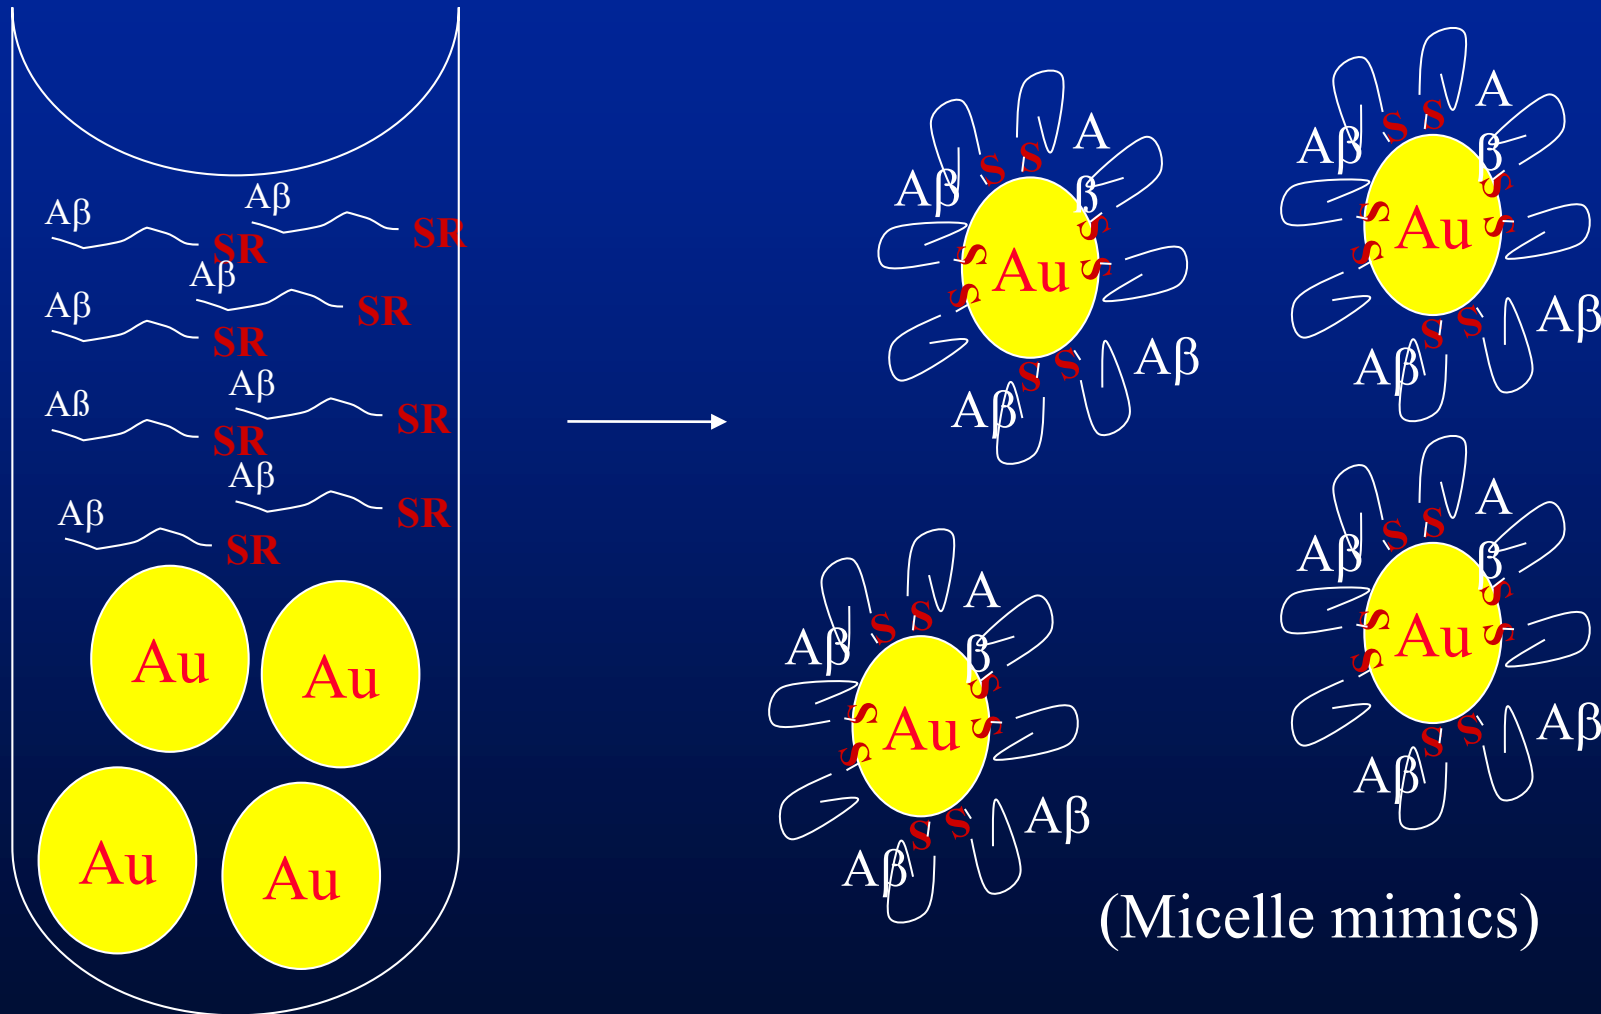

## ■ **Alzheimer's disease**

- Type II diabetes
- Parkinson's disease
- Huntington's disease
- Prion (Mad Cow's) disease
- Serum amyloidosis
- Familial Amyloid Polyneuropathy
- Macula Degeneration.
- Amyltropic Lateral Sclerosis
- Inclusion Body Myositis
- Idiopathic Cardiomyopathy

# Soluble Amyloid Oligomers are a Common Intermediate in Amyloid Fibril Formation.

# Antigen Preparation

# Anti-Oligomer antibody specificity

Dot blot

ELISA

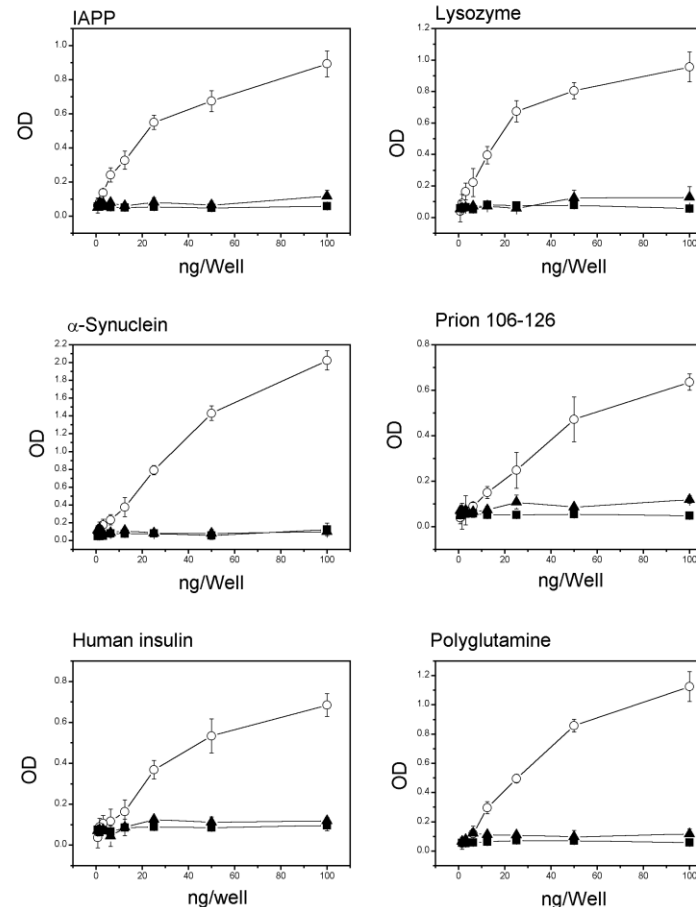

# Characteristics of immune response to A $\beta$ -gold oligomer mimics.

- The immune response is specific. No immunoreactivity against “normal” sequence dependent A $\beta$  epitopes after 12 injections.
- The immune response is long lasting: Titer does not drop significantly within 6 months after vaccination.
- Adjuvant is not required for high titer immune response.

# Anti-Oligomer antibody recognizes soluble oligomers from all other types of amyloids.

# Anti-Oligomer neutralizes the toxicity of all types of amyloid oligomers.

# Summary

- Immunization with a molecular mimic of A $\beta$  micelles produces a polyclonal antibody (Anti-Oligomer), that is specific for the soluble, high molecular weight micellar oligomeric intermediate that is common to all amyloids tested.
- Anti-Oligomer does not recognize APP, soluble monomeric A $\beta$  or fibrillar peptides.
- Anti-Oligomer neutralizes the toxicity of all types of oligomers.
- The fact that soluble amyloid oligomers have a common structure suggests that they share a common mechanism of toxicity and pathogenesis.

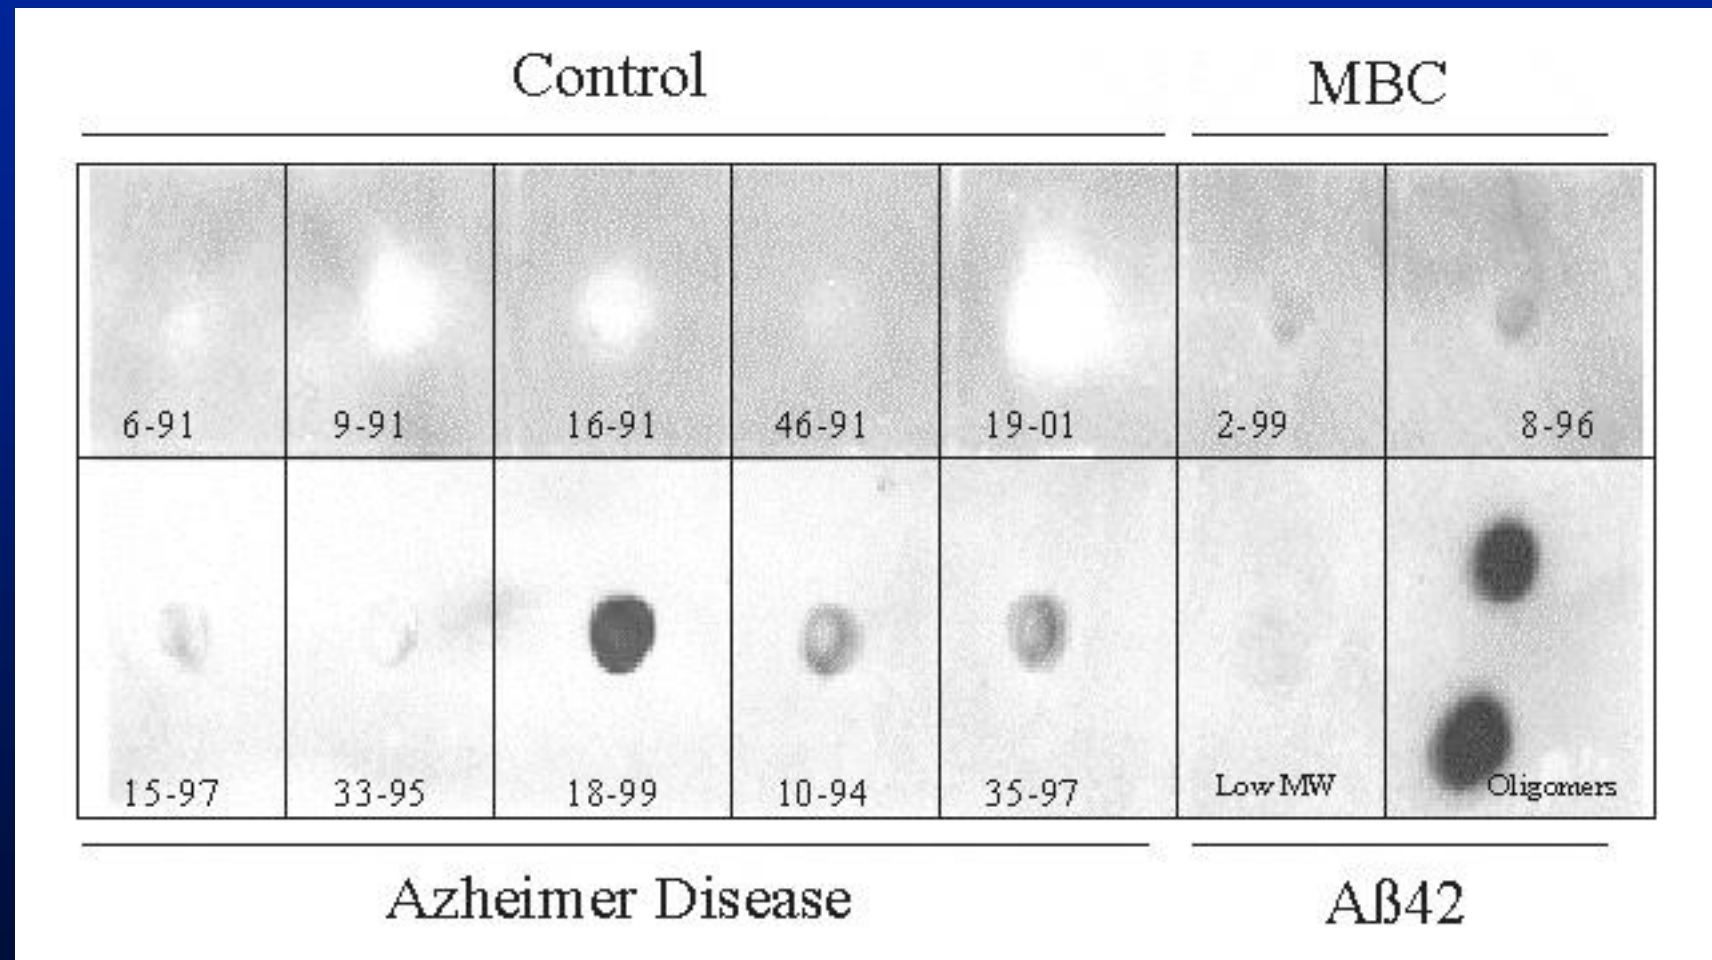

# Anti-Oligomer immuno-reactivity in human AD brain.

Red: Anti-Oligomer

Green: Thio S staining of amyloid fibers

# Oligomer levels in soluble extracts of human brain.

# Summary

- Anti-Oligomer stains small, focal deposits in AD and Tg mouse brain that are distinct from Thio-S positive and diffuse plaques.
- Anti-Oligomer immunoreactivity is elevated in AD brain.
- Oligomeric A $\beta$  represents a small fraction of the total A $\beta$ .

# Summary

- Vaccination with A $\beta$ -gold oligomer molecular mimics may be as effective as preventing amyloid accumulation as fibrillar A $\beta$ , but yet it may avoid the inflammatory complications associated with the first generation of Alzheimer's disease vaccine.

# Potential Applications

- The A $\beta$  oligomer molecular mimic antigen may be useful for development of a specific vaccine that avoids autoimmune and inflammatory complications.
- Anti-Oligomer antibody may be useful as a diagnostic tool to determine the levels of the soluble oligomers in biological fluids.
- The anti-Oligomer antibody may be a valuable specific surrogate marker to evaluate the therapeutic effectiveness of agents that are designed to decrease or eliminate the neurotoxic amyloid.
- Anti-Oligomer antibody may be useful for high-throughput screening for drugs that inhibit oligomer formation.

# Opportunities for Therapeutic and Diagnostic Development

	Diabetes Type II	Alzheimer's Disease	Mad Cow's Disease	Parkinson's Disease	Huntington's Disease	Serum amyloidosis
1. Vaccine	X	X	X	X	X	X
2. Drug Discovery	X	X	X	X	X	X
3. Diagnostic	X	X	X	X	X	X

A single focus on the common toxic oligomers provides a large number of opportunities for product development.
